# July 13, 1981

This list supplements previous errata published in Stanford reports CS551 (1976) and CS712 (1979). It includes the first corrections and changes to the second edition of volume two (published January, 1981) as well as to the most recent printings of volumes one and three (first published in 1975). In addition to the errors listed here, about half of the occurrences of 'which' in volumes one and three should be changed to 'that'.

1/80 2

here is a new Algorithm I together with a new Program I:

Algorithm I (Inverse in place). Replace X[1]X[2]...X[n], a permutation on  $\{1,2,...,n\}$ , by its inverse. This algorithm is due to Huang Bing-Chao.

- II. [Initialize.] Set  $m \leftarrow n, j \leftarrow -1$ .
- 12. [Next element.] Set  $i \leftarrow X[m]$ . If i < 0, go to step I5 (the element has already been processed).
- 13. [Invert one.] (At this point j < 0 and i = X[m]. If m is not the largest element of its cycle, the original permutation had X[-j] = m.) Set  $X[m] \leftarrow j$ ,  $j \leftarrow -m$ ,  $m \leftarrow i$ ,  $i \leftarrow X[m]$ .
- I4. [End of cycle?] If i > 0, go back to I3 (the cycle has not ended); otherwise set  $i \leftarrow j$ . (In the latter case, the original permutation has X[-j] = m, and m is largest in its cycle.)
- I5. [Store final value.] Set  $X[m] \leftarrow -i$ . (Originally X[i] was equal to m.)
- I6. (Loop on m, Decrease m by 1. If m > 0, go back to I2; otherwise the algorithm terminates.

For an example of this algorithm, see Table 2. The method is based on inversion of successive cycles of the permutation, tagging the inverted elements by making them negative, afterwards restoring the correct sign.

Table 2

COMPUTING THE INVERSE OF 621543 BY ALGORITHM I

(Read columns from left to right.) At point \*, the cycle (163) has been inverted.

					- ,			-	-	•	•

i	3	1	6	-1	-1	4	5	1	4	5	5	-6	-4	2	3

Algorithm I resembles parts of Algorithm A, and it very strongly resembles the cycle-finding algorithm in Program B (lines 50-64). Thus it is typical of a number of algorithms involving rearrangements. When preparing a MIX implementation, we find that it is most convenient to keep the value of -i in a register instead of i itself:

Program I (Inverse in place).  $rl1 \equiv m$ ;  $rl2 \equiv -i$ ;  $rl3 \equiv j$ ; and n = N, a symbol to be defined when this program is assembled as part of a larger routine.

The timing for this program is easily worked out in the manner shown earlier; every element X[m] is set first to a negative value in step 13 and later to a positive value in step 15. The total time comes to (14N+C+2)u, where N is the order of the permutation and C is the total number of cycles. The behavior of C in a random permutation is analyzed below.

There is almost always more than one algorithm ...

のできたいできたがあっていているというからないというからないというから、またいできたいできたがないできたが、またいかないなどのできたいからできないというできないというできます。 「「「「「「「「」」」

13. [22] Design an algorithm that begins with m weights  $w_1 \leq w_2 \leq \cdots \leq w_m$  and constructs an extended binary tree having minimum weighted path length. Represent the final tree in three arrays

$$A[1], \ldots, A[2m-1]; L[1], \ldots, L[m-1]; R[1], \ldots, R[m-1];$$

here L[i] and R[i] point to the left and right sons of internal node i, the root is node 1, and A[i] is the weight of node i. The original weights should appear as the external node weights  $A[m], \ldots, A[2m-1]$ . Your algorithm should make fewer than 2m weight-comparisons. Caution: Some or all of the given weights may be negative!

14. [25] (T. C. Hu and A. C. Tucker.) After k steps of Huffman's algorithm, the nodes combined so far form a forest of m-k extended binary trees. Prove that this forest has the smallest total weighted path length, among all forests of m-k extended binary trees that have the given weights.

15. [M25] Show that a Huffman-like algorithm will find an extended binary tree that minimizes (a)  $\max(w_1 + l_1, \ldots, w_m + l_m)$ ; (b)  $w_1 x^{l_1} + \cdots + w_m x^{l_m}$ , given x > 1.

16. [M25] (F. K. Hwang.) Let  $w_1 \leq \cdots \leq w_m$  and  $w_1' \leq \cdots \leq w_m'$  be two sets of weights with

$$\sum_{1 \le j \le k}^{\cdot} w_j \le \sum_{1 \le j \le k} w_j' \quad \text{for } 1 \le k \le m.$$

Prove that the minimum weighted path lengths satisfy  $\sum_{1 \le j \le m} w_j l_j \le \sum_{1 \le j \le m} w_j' l_j'$ .

17. [HM30] (C. R. Glassey and R. M. Karp.) Let  $s_1, \ldots, s_{m-1}$  be the numbers inside the internal (circular) nodes of an extended binary tree formed by Huffman's algorithm, in the order of construction. Let  $s_1', \ldots, s_{m-1}'$  be the internal node weights of any extended binary tree on the same set of weights  $\{w_1, \ldots, w_m\}$ , listed in any order such that each non-root internal node appears before its father. (a) Prove that  $\sum_{1 \le j \le k} s_j \le \sum_{1 \le j \le k} s_j'$  for  $1 \le k < m$ . (b) The result of (a) is equivalent to

$$\sum_{1 \leq j < m} f(s_j) \leq \sum_{1 \leq j < m} f(s'_j)$$

for every nondecreasing concave function f, i.e., every function f with  $f'(x) \geq 0$  and  $f''(x) \leq 0$ . [Cf. Hardy, Littlewood, and Polya, Messenger of Math. 58 (1929), 145-152.] Use this fact to study the recurrence

$$F(n) = f(n) + \min_{1 \le k \le n} (F(k) + F(n-k)), \qquad F(1) = 0,$$

given any function f(n) such that  $\Delta f(n) = f(n+1) - f(n) \ge 0$  and  $\Delta^2 f(n) = \Delta f(n+1) - \Delta f(n) \le 0$ .

#### 1.420 new paragraph before the exercises

2/7/70 47

Daniel P. Friedman and David S. Wise have observed that the reference counter method can be employed satisfactorily in many cases even when lists point to themselves, if certain link fields are not included in the counts [Inf. Proc. Letters 8 (1979), 41-45].

# 1.498 new answer to 1.2.11.2-3, overrides 1976 change #104 10/15/79

3.  $|R_{2k}| \leq |B_{2k}/(2k)!| \int_1^n |f^{(2k)}(x) dx|$ . [Notes: We have  $B_m(x) = (-1)^m B_m(1-x)$ , and  $B_m(x)$  is m! times the coefficient of  $x^m$  in  $xe^{xx}/(e^x-1)$ . In particular, since  $e^{x/2}/(e^x-1) = 1/(e^{x/2}-1) - 1/(e^x-1)$  we have  $B_m(\frac{1}{2}) = (2^{1-m}-1)B_m$ . It is not difficult to prove that the maximum of  $|B_{2m}-B_{2m}(x)|$  for  $0 \leq x \leq 1$  occurs at  $x=\frac{1}{2}$ . Now when  $k \geq 2$  we have  $R_{2k-2} = C_{2k} + R_{2k} = \int_1^n (B_{2k} - B_{2k}(\{x\})) f^{(2k)}(x) dx/(2k)!$ , and  $B_{2k} - B_{2k}(\{x\})$  is between 0 and  $(2-2^{1-2k})B_{2k}$ , hence  $R_{2k-2}$  lies between 0 and  $(2-2^{1-2k})C_{2k}$ . It follows that  $R_{2k}$  lies between  $-C_{2k}$  and  $(1-2^{1-2k})C_{2k}$ , a slightly stronger result. According to this argument we see that if  $f^{(2k+2)}(x)f^{(2k+4)}(x) > 0$  for 1 < x < n, the quantities  $C_{2k+2}$  and  $C_{2k+4}$  have opposite signs, while  $R_{2k}$  has the sign of  $C_{2k+2}$  and  $R_{2k+2}$  has the sign of  $C_{2k+4}$  and  $|R_{2k+2}| \leq |C_{2k+2}|$ ; this proves (13). Cf. J. F. Steffensen, Interpolation (Baltimore: 1927), §14.]

This formula ... n = 4.

(The constant A is "Glaisher's constant" 1.28242..., which equals  $(2\pi e^{\gamma-\epsilon'(2)/\epsilon(2)})^{1/12}$ ; cf. F. W. J. Olver, Asymptotics and Special Functions (New York: Academic Press, 1974), Section 8.3.3.)

#### $1.501\,$ new answer

/81 *61* 

18. Let  $S_n(x,y) = \sum {n \choose k} (x+k)^k (y+n-k)^{n-k}$ . Then for n>0 we have  $S_n(x,y) = x \sum {n \choose k} (x+k)^{k-1} (y+n-k)^{n-k} + n \sum {n-1 \choose k} (x+1+k)^k (y+n-1-k)^{n-k-k} = (x+y+n)^n + n S_{n-1}(x+1,y)$  by Abel's formula 1.2.6-16; consequently  $S_n(x,y) = \sum {n \choose k} k! (x+y+n)^{n-k}$ . [This formula is due to Cauchy, who proved it by quite different means in Exercices de Mathématiques (Paris: 1826), 62-73.] The stated sums are therefore equal respectively to  $n^n(1+Q(n))$  and  $(n+1)^n Q(n+1)$ .

18/79

63

Historical notes: C. Haros gave a (more complicated) rule for constructing such sequences, in J. de l'École Polytechnique 4, 11 (1802), 364-368; his method was correct, but his proof was inadequate. The geologist John Farey independently conjectured several years later that  $x_k/y_k$  is always equal to  $(x_{k-1} + x_{k+1})/(y_{k-1} + y_{k+1})$  [Philos. Magazine and Journal 47 (1816), 385-386]; a proof was supplied shortly afterwards by A. Cauchy [Bull. Société Philomathique de Paris (3) 3 (1816), 133-135], who attached Farey's name to the series. For more of its interesting properties,

X's. For the history of the ballot problem $\wedge \rightarrow X$ 's. This problem was actually resolved as early as 1708 by Abraham de Moivre, who showed that the number of sequences containing $l$ A's and $m$ B's, and containing at least one initial substring with $n$ more A's than B's, is $f(l, m, n) = \binom{l+m}{\min(m, l-n)}$ . In particular, $a_n = \binom{2n}{n} - f(n, n, 1)$ as above. (De Moivre stated this result without proof [Philos. Trans. 27 (1711), 262-263]; but it is clear from other passages in his paper that he knew how to prove it, since the formula is obviously true when $l \geq m+n$ , and since his generating-function approach to similar problems yields the symmetry condition $f(l, m, n) = f(m+n, l-n, n)$ by simple algebra.) For the later history of the ballot problem	
$1.538$ insert new answer 3/1/70 $ extit{6}$ .	5
13. A. C. Yao has shown that $\max(k_1, k_2)$ will be $\frac{1}{2}m + (2\pi(1-2p))^{-1/2}\sqrt{m} + O(m^{-1/2}(\log m)^2)$ for large $m$ , when $p < \frac{1}{2}$ . [SIAM J. Computing 10 (1981), 398-403.]

10/18/79 86

(place the figure at the right margin and set the copy narrower, to its left)

The desired ternary tree is

The desired ternary tree is shown at the right. F. K. Hwang has observed [SIAM J. Appl. Math. 37 (1979), 124-127] that a similar procedure is valid for minimum weighted path length trees having any prescribed multiset of degrees: at each step the smallest t weights are combined, where t is as small as possible.

#### 1.590 new answers replacing answer 12

87

12. By exercise 9, it is the internal path length divided by n. [This holds for general trees as well.]

13. [Cf. J. van Leeuwen, Proc. 3rd International Colloq. Automata, Languages, and Programming, Edinburgh (July 1976), 382-410.]

**H1.** [Initialise.] Set  $A[m-1+i] \leftarrow w_i$  for  $1 \le i \le m$ . Then set  $x \leftarrow m$ ,  $i \leftarrow m+1$ ,  $j \leftarrow m-1$ ,  $k \leftarrow m$ . (During this algorithm  $A[i] \le \cdots \le A[2m-1]$  is the queue of unused external weights and  $A[k] \ge \cdots \ge A[j]$  is the queue of unused internal weights; the current left and right pointers are x and y.)

**H2.** [Find right pointer.] If j < k or  $A[i] \le A[j]$ , set  $y \leftarrow i$  and  $i \leftarrow i + 1$ ; otherwise set  $y \leftarrow j$  and  $j \leftarrow j - 1$ .

**H3.** [Create internal node.] Set  $k \leftarrow k-1$ ,  $L[k] \leftarrow x$ ,  $R[k] \leftarrow y$ ,  $A[k] \leftarrow A[x] + A[y]$ .

II4. [Done?] Terminate the algorithm if k = 1.

**H5.** [Find left pointer.] (At this point  $j \ge k$  and the queues contain a total of k unused weights. If A[y] < 0 we have j = k, i = y + 1, and A[i] > A[j].) If  $A[i] \le A[j]$ , set  $x \leftarrow i$  and  $i \leftarrow i + 1$ ; otherwise set  $x \leftarrow j$  and  $j \leftarrow j - 1$ . Return to step H2.

14. The proof for k = m - 1 applies with little change. [Cf. SIAM J. Appl. Math. 21 (1971), 518.]

15. Use the combined-weight functions (a)  $1 + \max(w_1, w_2)$  and (b)  $x(w_1 + w_2)$ , respectively, instead of  $w_1 + w_2$  in (9). [Part (a) is due to M. C. Golumbic, IEEE Trans. C-25 (1976), 1164-1167; part (b) to T. C. Hu, D. Kleitman, and J. K. Tamaki, SIAM J. Appl. Math. 37 (1979), 246-256. Part (a) may be considered as the limiting case of part (b) as  $x \to \infty$ ; Huffman's problem is, similarly, the limiting case as  $x \to 1$ , since  $\sum (1+\epsilon)^l w_l = \sum w_l + \epsilon \sum w_l l_l + O(\epsilon^2)$ .]

D. Stott Parker, Jr., has pointed out that a Huffman-like algorithm will also find the minimum of  $w_1x^{i_1} + \cdots + w_mx^{i_m}$  when 0 < x < 1, if the two maximum weights are combined at each step. In particular, the minimum of  $w_12^{-i_1} + \cdots + w_m2^{-i_m}$ , when  $w_1 \le \cdots \le w_m$ , is  $w_1/2 + \cdots + w_{m-1}/2^{m-1} + w_m/2^{m-1}$ .

16. Let  $l_{m+1} = l'_{m+1} = 0$ . Then

$$\sum_{1 \le j \le m} w_j \, l_j \le \sum_{1 \le j \le m} w_j \, l_j' = \sum_{1 \le k \le m} (l_j' - l_{j+1}') \sum_{1 \le j \le k} w_j$$

$$\le \sum_{1 \le k \le m} (l_j' - l_{j+1}') \sum_{1 \le j \le k} w_j' = \sum_{1 \le j \le m} w_j' \, l_j',$$

since  $l'_j \ge l'_{j+1}$  as in exercise 4. The same proof holds for many other kinds of optimum trees, including those of exercise 10.

17. (a) This is exercise 14. (b) We can extend f(n) to a concave function f(x), so the stated inequality holds. Now F(m) is the minimum of  $\sum_{1 \le j < m} f(s_j)$ , where the  $s_j$  are internal node weights of an extended binary tree on the weights 1, 1, ..., 1. Huffman's algorithm, which constructs the complete binary tree with m-1 internal nodes in this case, yields the optimum tree. Therefore the choice  $k=2^{\lceil \lg n/3 \rceil}$  yields the minimum in the recurrence, for each n. [Reference: SIAM J. Appl. Math. 31 (1976), 368-378. We can evaluate F(n) in  $O(\log n)$  steps; cf. exercises 5.2.3-20 and 21. If f(n) is convex instead of concave, so that  $\Delta^2 f(n) \ge 0$ , the solution to the recurrence is obtained when  $k = \lfloor n/2 \rfloor$ .

#### 1.603 new version of lines ?2-24 (overrides previous changes) 10/18/70

[This method is called the "LISP 2 garbage collector." An interesting alternative, which does not require the LINK field at the beginning of a node, can be based on the idea of linking together all pointers that point to each node—see Lars-Erik Thorelli, BIT 16 (1976), 426-441; F. Lockwood Morris, CACM 21 (1978), 662-665, 22 (1979), 571; and H. B. M. Jonkers, Inf. Proc. Letters 9 (1979), 26-30. Other methods have been published by B. K. Haddon and W. M. Waite, Comp. J. 10 (1967), 162-165; B. Wegbreit, Comp. J. 15 (1972), 204-208; D. A. Zave, Inf. Proc. Letters 3 (1975), 167-169.]

42. We can assume that  $m \ge 6$ . The main idea is to establish the occupancy pattern  $R_{m-2}(F_{m-3}R_1)^k$  at the beginning of the memory, for  $k=0, 1, \ldots$ , where  $R_j$  and  $F_j$  denote reserved and free blocks of size j. The transition from k to k+1 begins with

$$R_{m-2}(F_{m-3}R_1)^k \to R_{m-2}(F_{m-3}R_1)^k R_{m-2}R_{m-2}$$

$$\to R_{m-2}(F_{m-3}R_1)^{k-1}F_{2m-4}R_{m-2}$$

$$\to R_{m-2}(F_{m-3}R_1)^{k-1}R_m R_{m-5}R_1R_{m-2}$$

$$\to R_{m-2}(F_{m-3}R_1)^{k-1}F_m R_{m-5}R_1;$$

then the commutation sequence  $F_{m-3}R_1F_mR_{m-5}R_1 \to F_{m-3}R_1R_{m-2}R_2R_{m-5}R_1 \to F_{2m-4}R_2R_{m-5}R_1 \to R_mR_{m-5}R_1R_2R_{m-5}R_1 \to F_mR_{m-5}R_1F_{m-3}R_1$  is used k times until we get  $F_mR_{m-5}R_1(F_{m-3}R_1)^k \to F_{2m-5}R_1(F_{m-3}R_1)^k \to R_{m-2}(F_{m-3}R_1)^{k+1}$ . Finally when k gets large enough there is an endgame that forces overflow unless the memory size is at least (n-4m+11)(m-2); details appear in Comp. J. 20 (1977), 242-244. [Note that the worst conceivable worst case, which begins with the pattern  $F_{m-1}R_1F_{m-1}R_1F_{m-1}R_1\dots$ , is only slightly worse than this; the next-fit strategy of exercise 6 can produce this pattern.]

43. We will show that if  $D_1, D_2, \ldots$  is any sequence of numbers such that  $D_1/m + D_2/(m+1) + \cdots + D_m/(2m-1) \ge 1$  for all  $m \ge 1$ , and if  $C_m = D_1/1 + D_2/2 + \cdots + D_m/m$ , then  $N_{\rm FF}(n,m) \le nC_m$ . In particular, since

$$\frac{1}{m} + \frac{1}{m+1} + \dots + \frac{1}{2m-1} = 1 - \frac{1}{2} + \dots + \frac{1}{2m-3} - \frac{1}{2m-2} + \frac{1}{2m-1} > \ln 2,$$

the constant sequence  $D_m=1/(\ln 2)$  satisfies the necessary conditions. The proof is by induction on m. Let  $N_j=nC_j$  for  $j\geq 1$ , and suppose that some request for a block of size m cannot be allocated in the leftmost  $N_m$  cells of memory. Then m>1. For  $0\leq j< m$ , we let  $N_j'$  denote the rightmost position allocated to blocks of sizes  $\leq j$ , or 0 if all reserved blocks are larger than j; by induction we have  $N_j'\leq N_j$ . Furthermore we let  $N_m'$  be the rightmost occupied position  $\leq N_m$ , so that  $N_m'\geq N_m-m+1$ . Then the interval  $(N_{j-1}',N_j')$  contains at least  $\lceil j(N_j'-N_{j-1}')/(m+j-1)\rceil$  occupied cells, since its free blocks are of size < m and its reserved blocks are of size  $\geq j$ . It follows that  $n-m\geq n$  number of occupied cells  $\geq \sum_{1\leq j\leq m} j(N_j'-N_{j-1}')/(m+j-1)=mN_m'/(2m-1)-(m-1)\sum_{1\leq j< m} N_j'/(m+j)(m+j-1)>mN_m/(2m-1)-m-(m-1)\sum_{1\leq j< m} N_j(1/(m+j-1)-1/(m+j))=\sum_{1\leq j\leq m} nD_j/(m+j-1)-m\geq n-m$ , a contradiction.

[This proof establishes slightly more than was asked. If we define the D's by  $D_1/m + \cdots + D_m/(2m-1) = 1$ , then the sequence  $C_1, C_2, \ldots$  is 1,  $\frac{7}{4}$ ,  $\frac{161}{72}$ ,  $\frac{7483}{72}$ ,  $\ldots$ ; and the result can be improved further, even in the case m = 2, cf. exercise 38.]

# 3.544 exercise 14 (replacement for lines 3 and following) 2/23/79 351

2-bit TAG field and two link fields called LINK and AUX, with the following interpretation:

- TAG(P) == 0 indicates a word in the list of available space; LINK(P) points to the next entry in this list, and AUX(P) is unused.
- TAG(P) = 1 indicates any word in use where P is not the hash address of any key in the scatter table; the other fields of the word in location P may have any desired format.
- TAG(P) = 2 indicates that P is the hash address of at least one key; AUX(P) points to a linked list specifying all such keys, and LINK(P) points to another word in the list memory. Whenever a word with TAG(P) = 2 is accessed during the processing of any list, it is necessary to set  $P \leftarrow LINK(P)$  repeatedly until reaching a word with TAG(P)  $\leq 1$ . (For efficiency we might also then change prior links so that it will not be necessary to skip over the same scatter table entries again and again.)

Show how to define suitable algorithms for inserting and retrieving keys in a combined table of this sort.

#### 3.546 replacements for exercises 34(c), 35, 36

/10/80 353

- (c) Express the average number of probes for a successful search in terms of this generating function. (d) Deduce the average number of probes in an unsuccessful search, considering variants of the data structure in which the following conventions are used: (i) hashing is always to a list head (cf. Fig. 38); (ii) hashing is to a table position (cf. Fig. 40), but all keys except the first of a list go into a separate overflow area; (iii) hashing is to a table position and all entries appear in the hash table.
- 35. [M24] Continuing exercise 34, what is the average number of probes in an unsuccessful search when the individual lists are kept in order by their key values? Consider data structures (i), (ii), and (iii).
- 36. [M23] Continuing exercise 34(d), find the variance of the number of probes when the search is unsuccessful, using data structures (i) and (ii).

#### $3.546\,$ new wording of exercises 37 and 40

/10/80 354

- ▶ 37. [M29] Eq. (19) gives the average number of probes in separate chaining when the search is successful; what is the variance of this quantity?
- 40. [M33] Eq. (15) gives the average number of probes used by Algorithm C in an unsuccessful search; what is the variance of this quantity?

#### $3.546\,$ new wording for exercise 39 (keep the old last line)

1/80 355

39. [M27] Let  $c_N(k)$  be the total number of lists of length k formed when Algorithm C is applied to all  $M^N$  hash sequences (35). Find a recurrence relation on the numbers  $c_N(k)$  that makes it possible to determine a simple formula for the sum

$$S_N = \sum_{k} \binom{k}{2} c_N(k).$$

lines 4 and 5:  $C'_N$  ... all keys.  $\longrightarrow$  Consider the total number of probes to find all keys, not counting the fetching of the pointer in the list head table of Fig. 38 if such a table is used.

#### 3.693 new answer 35

10/80 *380* 

35. (i)  $\sum (1 + \frac{1}{2}k - (k + 1)^{-1})P_{Nk} = 1 + N/2M - M(1 - (1 - 1/M)^{N+1})/(N+1) \approx 1 + \frac{1}{2}\alpha - (1 - e^{-\alpha})/\alpha$ . (ii) Add  $\sum \delta_{k0}P_{Nk} = (1 - 1/M)^N \approx e^{-\alpha}$  to the result of (i). (iii) Assume that when an unsuccessful search begins at the jth element of a list of length k, the given key has random order with respect to the other k elements, so the expected length of search is  $(j \cdot 1 + 2 + \cdots + (k+1-j) + (k+1-j))/(k+1)$ . Summing on j now gives  $MC_N' = M - N + M\sum_{i=1}^{N}(k^3 + 9k^2 + 2k)P_{Nk}/6(k+1) = M - N + M(\frac{1}{6}N(N-1)/M^2 + \frac{3}{2}N/M - 1 + (M/(N+1))(1 - (1-1/M)^{N+1}))$ ; hence  $C_N' \approx \frac{1}{2}\alpha + \frac{1}{6}\alpha^2 + (1 - e^{-\alpha})/\alpha$ .

#### 3.693 answer 36

6/6/80 381

line 1, replace first sentence by: (i)  $N/M - N/M^2$ . (ii)  $\sum (\delta_{k0} + k)^2 P_{Nk} = \sum (\delta_{k0} + k^2) P_{Nk} = P_N(0) + P_N'(1) + P_N'(1)$ .

line -1, add new remark: [For data structure (iii), a more complicated analysis like that in exercise 37 would be necessary.]

# 3.694 replacement for lines 1-3 and big display of answer 39 $_{6/1/80}$ 382

39. (This approach to the analysis of Algorithm C was suggested by J. S. Vitter.) We have  $c_{N+1}(k) = (M-k)c_N(k) + (k-1)c_N(k-1)$  for  $k \ge 2$ , and furthermore  $\sum kc_N(k) = NM^N$ . Hence  $S_{N+1} = \sum_{k\ge 2} {k \choose 2} c_{N+1}(k) = \sum_{k\ge 2} {k \choose 2} ((M-k)c_N(k) + (k-1)c_N(k-1)) = \sum_{k>1} [(M+2){k \choose 2} + k)c_N(k) = (M+2)S_N + NM^N$ .

# 3.694 line 1 of answer 40

5/1/80 383

 $\binom{j}{2}$  replaced by  $\binom{j+1}{3}$ .  $\bigwedge$   $\binom{k}{2}$  replaced by  $\binom{k+1}{3}$ .

# 3.694 new answer

16/80 *384* 

43. Let  $N = \alpha M'$  and  $M = \beta M'$ , and let  $e^{-\lambda} + \lambda = 1/\beta$ ,  $\rho = \alpha/\beta$ . Then  $C_N \approx 1 + \frac{1}{2}\rho$  and  $C'_N \approx \rho + e^{-\rho}$ , if  $\rho \leq \lambda$ ;  $C_N \approx \frac{1}{8\rho}(e^{2(\rho-\lambda)} - 1 - 2(\rho-\lambda))(3 - 2/\beta + 2\lambda) + \frac{1}{4}(\rho + \lambda) + \frac{1}{4}\lambda(1 - \lambda/\rho)$  and  $C'_N \approx 1/\beta + \frac{1}{4}(e^{2(\rho-\lambda)} - 1)(3 - 2/\beta + 2\lambda) - \frac{1}{4}(\rho - \lambda)$ , if  $\rho \geq \lambda$ . For  $\alpha = 1$  we get the smallest  $C_N \approx 1.69$  when  $\beta \approx .853$ ; the smallest  $C'_N \approx 1.79$  occurs when  $\beta \approx .782$ . So it pays to put the first collisions into an area that doesn't conflict with hash addresses, even though a smaller range of hash addresses causes more collisions to occur. These results are due to Jeffrey S. Vitter [Ph.D. thesis, Stanford Univ. (1980); Proc. Symp. Foundations Comp. Sci. 21 (1980), 238-247].
